

The Efficiency of Using Building Integrated Photovoltaics in the Retrofitting of Office Buildings in Egypt

Maha Anber ¹

ABSTRACT

The use of Photovoltaic (PV) technology has spread recently due to its significant contribution to the generation of energy as well as reducing the carbon footprint of buildings. The different materials of the building envelope contribute differently to the energy consumption of the building concerning heat transfer. This research paper aims at studying the efficiency of integrating Building Integrated Photovoltaics (BIPV) in the building skin to reduce energy consumption rates and reduce admitted solar heat gain. This study includes an energy simulation study using an energy simulation software to hold a numerical comparative study between two different types of Building Integrated Photovoltaics (BIPV) that are integrated into the building skin to contribute to reducing the energy demand by the building to determine the most efficient type. Moreover, the research states the feasibility of using them as it is tested along with the payback period of the initial cost of installing them.

Keywords: Building integrated photovoltaics (BIPV), Energy simulation, Building envelope, DesignBuilder Software, Payback period

INTRODUCTION

Atlas Solar radiation of Egypt stated that the annual daily direct solar radiation of Egypt from North to South varies between 5.4 and 7.1 KWh/m² [1]. According to the German Aerospace Center evaluation of Egypt's sufficiency of solar potential was estimated by nearly 74 Billion MWh/year [1]. The great potential of Egypt in Solar radiation rates is considered a promising investment aspect not only in economical way but also as an environmental concern by reducing the Carbon Dioxide emissions by substituting oil and coal power stations with renewable energy sources. Although Egypt has massive energy production, its domestic energy consumption rates are high which results on depending on importing hydrocarbon products which negatively affects not only the economy of Egypt but the environment as it results in multiple negative environmental effects[2].

Office buildings consume around 40% of their energy for lighting to provide an adequate visual environment for their occupant [3]. As shown in figure 1, the energy consumption in Egypt by sector which show that building sector by all its services consume a great sum of energy.

Large glazed curtain walls provide adequate natural light for occupants to achieve indoor visual comfort. Depending on natural light increases productivity and performance of

users according to many research studies. According to Y. Al Horr, et al (2017), daylighting is the best light source for human visual comfort as well as having a positive impact on improving people's behavior [4]. Another research stated that daylighting improves mental function and reduces depression and violent behavior [5]. It also improves the psychological status of space users. Daylight was proven to have a natural effect of healing due to the connection to the world outside which enhances the connection to nature and results in boosting the occupants' mood [6].

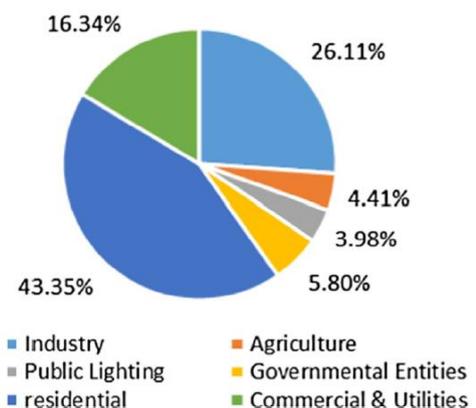

Figure 1: energy consumption in Egypt [4]

Using large glazed building facades causes significant heat transfer, which increases the cooling loads and likewise the energy consumption [7]. Building envelopes hold great potential concerning energy savings as they can

DOI: [10.21608/PSERJ.2021.64601.1095](https://doi.org/10.21608/PSERJ.2021.64601.1095)

be integrated with renewable energy generation tools to provide energy for the buildings as well as to decrease the negative environmental impact of fossil energy.

Fully glazed facades are responsible for almost 45% of the cooling demand of buildings [8]. Large, glazed facades result in great energy consumption rates and cause thermal discomfort as they allow for the access of more solar gain [9]. Glazed facades components have great influence on the energy consumption reflected on the air conditioning system and determined by the glazing area, type of glazing and orientation [10].

1. BUILDING ENERGY RETROFIT

Building energy retrofit is the renovation or refurbishment of existing buildings to upgrade their energy performance [11]. The inefficiency of existing buildings must be addressed to achieve building sustainability [12]. Applying building energy retrofit measures to reduce the energy inefficiency of buildings and has proven great impact on reducing total energy consumption [13]. According to Luisa F. Cabeza, et al. (2018), in order to achieve energy efficiency in buildings, multiple researches addressed incorporating renewable energy to reduce their carbon footprint and to improve their indoor air quality [14]. S. Attia et al. (2009) stated that among retrofitting strategies, using photovoltaic panels in new and existing buildings can achieve great reduction in electric energy demand [15].

2. BUILDING INTEGRATED PHOTOVOLTAIC (BIPV)

BIPV applications can be used on multiple elements of the building envelope such as walls, roofs, and skylights [16]. BIPV systems can operate as an element of the building envelope material and a source generating electricity. They reduce both fossil fuel consumption and greenhouse gas emissions. Moreover, when they are used as a building skin, they achieve materials cost savings [17]. Photovoltaic glazing is a modern innovation in the technology of building glazing that allows the window to keep its functional role besides providing the building with an energy source [18].

Egypt has recently developed an incentive program for people to invest in renewable energy projects and especially photovoltaic cells. These incentives include the reduction of customs for any devices and tools used for renewable energy, fund facilities for renewable energy installations and equipping the national domestic grid with new installations and connections to accommodate renewable energy technologies [19]. In Egypt, installing the photovoltaic system in a high energy consuming project is expected to have payback over a period of five to eight years which is considered very good in terms of investment [20].

3. CASE STUDY

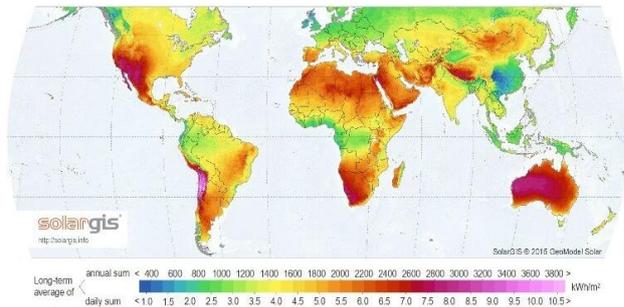

Figure 2: Solar radiation around the world [16]

The research case study was held in an office building located in New Cairo, Cairo, Egypt. As shown in figures three and four, the office-building external glazed facade and its location in new Cairo. The office building is the headquarters of the National Bank of Egypt (NBE). Cairo is chosen as the case study location as it is the capital of Egypt with the largest number of office buildings. It holds a great potential for the use of solar energy applications as means of using renewable energy resources due to its location in hot arid zone according to the world's climate classification with high average solar radiation levels according to Solar GIS as shown in figure number 2 [21], the solar radiation in Egypt is between 5.4 to 7.1 kWh/m² from north [22].

Figure 3: National Bank of Egypt headquarters location- By researcher

Figure 4: National Bank of Egypt- By researcher

4.1. Cairo Climate Summary

Cairo is located 29 meters above sea level. Its climate is a desert climate and there is no rainfall during the whole year except for a very limited amount in limited months. This climate is categorized under Hot Desert Climate according to Köppen-Geiger climate classification of the world.

The National Bank of Egypt (NBE) building is located in 30°01'02.30" East, "49.67'58°63 North. It is one of the headquarters of the bank accommodating around 700 employees and it has branch dealing with public and an ATM machine.

4.2. Building Information

Type: Office building
 Owner: National Bank of Egypt
 Designer: APG architecture and planning group

The building's total area is 11064 m² while its footprint is 1700 m². It is a seven-storey building with two basement floors of the parking that are specified for the employees accommodating around 200 cars. The basement floor as well has an armoured room for storing shares and stocks of the bank customers. The bank is an open plan office building that allows various modulation of workspaces. The large curtain wall glazing, with properties mentioned in table 1, allows the maximum penetration of natural daylight as one of the key requirements of a healthy indoor working environment. Solid walls are used in service areas, control rooms and emergency stairs.

Table 1: Curtain wall glass properties- Engineering Administration National Bank of Egypt

Glass Type	U- Value (Thermal Transmittance) W/m ² .K	SHGC (Solar Heat Gain Coefficient)	LT (Light Transmission)
Single glass 6 mm	6.17	0.88	0.82

5. METHODOLOGY

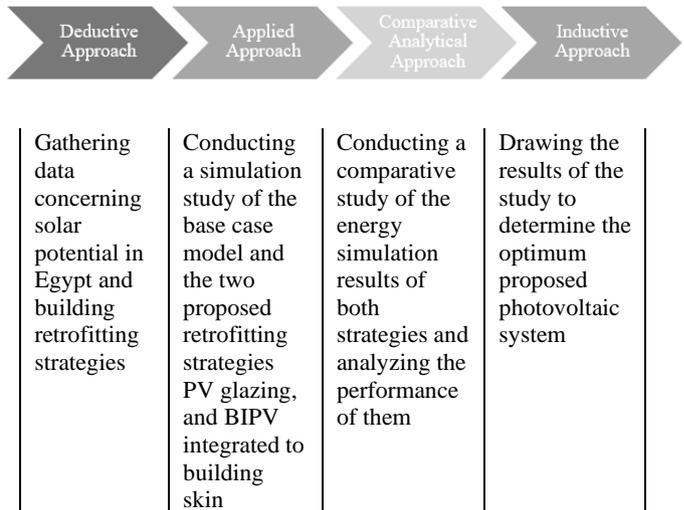

Figure 6: Research Methodology

The methodology that is based on Building Performance Simulation (BPS) depends on modelling the bank building so as to determine the optimum retrofit strategy through numerical simulations which results in a repeated process of retrofitting so as to reach the best retrofit strategy [23] as shown in figure 7.

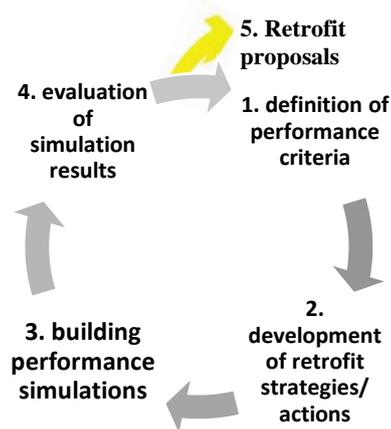

Figure 7: Building performance simulation-based process [13]

The research methodology is initialized by modelling the National Bank of Egypt headquarters located in the fifth settlement, New Cairo, Egypt in Design Builder software.

The modelling of the building includes the input of all the data of the building construction, building envelope consisting of fenestration, glazing walls, roof, as well as HVAC system, activities, finishing materials, lighting fixtures and appliances.

The applied study is divided into three stages;

5.1. Stage One

The energy simulation of Base case model on DesignBuilder software to determine the actual annual energy consumption of the building. As shown in figure 8, the base case model in DesignBuilder software where all the building data were inserted and modeled. Building materials, activity in all spaces, glazing type and HVAC system were modeled to calculate the actual annual energy consumption.

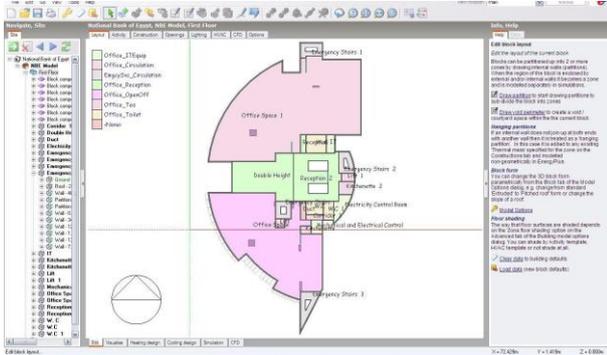

Figure 8: NBE First Floor plan on DesignBuilder software- By researcher

5.2. Stage Two

Integrating the Photovoltaics within the building skin on the south elevation with BISOL XL Series, Multicrystalline PV modules/ BXU 340 Wp. The thermal, electrical and mechanical specifications are shown in Table 2. These specifications were input in the simulation process so as to determine the energy performance of the substitution of the building skin with Photovoltaic modules. The substituted area from the project’s skin to the Photovoltaic modules will be on an area of 680.74 m².

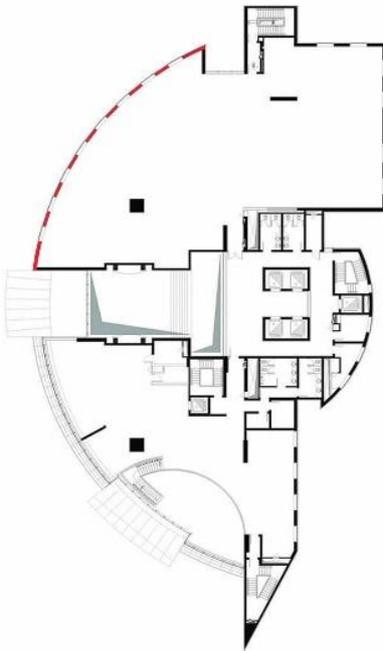

Figure 9: The selected building envelope to be covered by PV modules

Table 2: BISOL XL Series, Multicrystalline PV modules/ BXU 340 Wp Thermal, mechanical and electrical specifications [17]

Mechanical Specifications	
Length x Width X Thickness	1.966 mm x 991 mm x 40 mm
Weight	22 kg
Solar Cells	72 multi c-Si in series / 156 mm X 156 mm (6+’')
Junction Box / Connectors	Three bypass diodes / MC4 compatible / IP 67
Thermal Specifications	
Module efficiency η_M (%)	17.5
Solar Cell efficiency η_c (%)	19.2
Electrical Specifications	
MPP Voltage V_{MPP} [V]	37.2
Nominal Power P_{MPP} [W]	340

5.3. Stage Three

Table 3: Jonsol JSM-72, Thermal, mechanical and electrical specifications [Error! Bookmark not defined.]

Mechanical Specifications	
Length x Width X Thickness	1.956 mm x 992 mm x 40 mm
Weight	24 kg
Junction Box / Connectors	PV- GF20, IP67, 3 diodes
Thermal Specifications	
Module efficiency η_M (%)	17.3
Solar Cell efficiency η_c (%)	19
Electrical Specifications	
MPP Voltage V_{MPP} [V]	38.87
Nominal Power P_{MPP} [W]	335

6. RESULTS

6.1. Simulation Results for Stage 1

The simulation of the base case model of the building shows that the annual energy consumption rate is 1414229 KW.h as shown in figure 11.

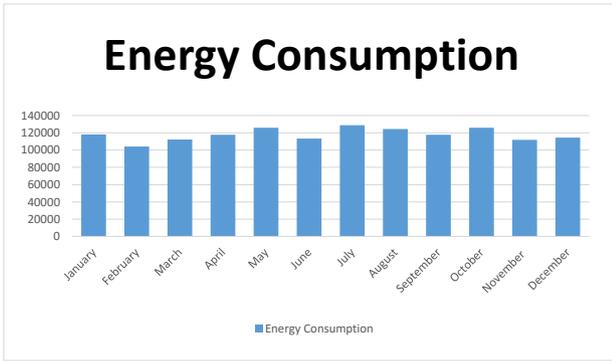

Figure 10: Base case monthly energy consumption simulated on DesignBuilder software- By researcher

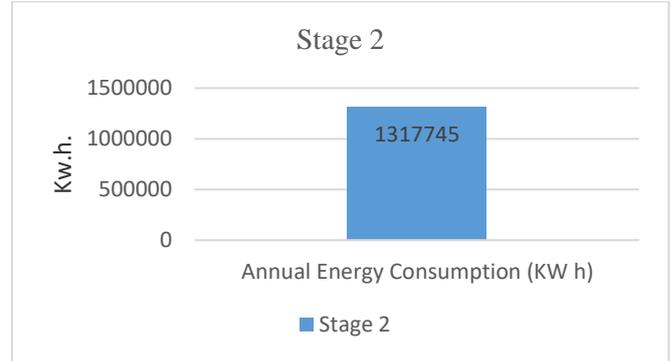

Figure 13: Stage 2 annual energy consumption simulated on DesignBuilder software- By researcher

The simulation of stage 2, integrating the BISOL XL Series, Multicrystalline PV modules/ BXU 340 Wp in the elevation resulted in an annual energy consumption reduction from 1414229 to 1317745 KW.h. of the total energy consumption as shown in figure number 13.

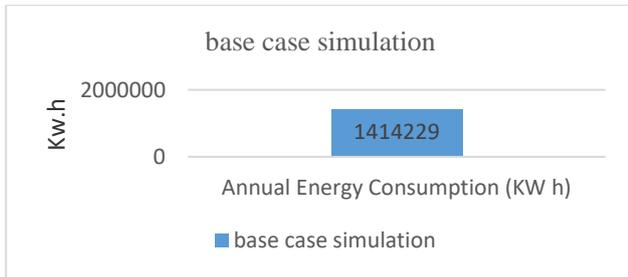

Figure 11: Base case (stage 1) annual energy consumption simulated on DesignBuilder software- By researcher

The simulation of the base case model of the building shows that the annual energy consumption rate is 1414229 KW.h.

6.2. Simulation Results for Stage 2

The integration of the BISOL XL PV modules with cell efficiency 19.2% in the building skin on an area of 680.74 m2 resulted in the following reductions. The annual energy consumption was reduced from 1414229 KW.h to 1317745 KW.h with a reduction of 6.9%.

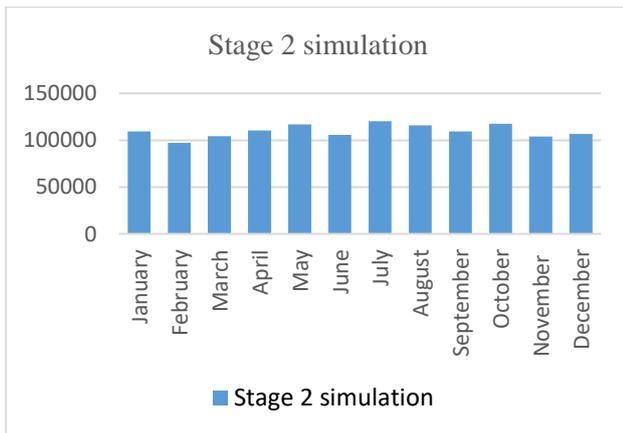

Figure 12: Stage 2 monthly energy consumption simulated on DesignBuilder software- By researcher

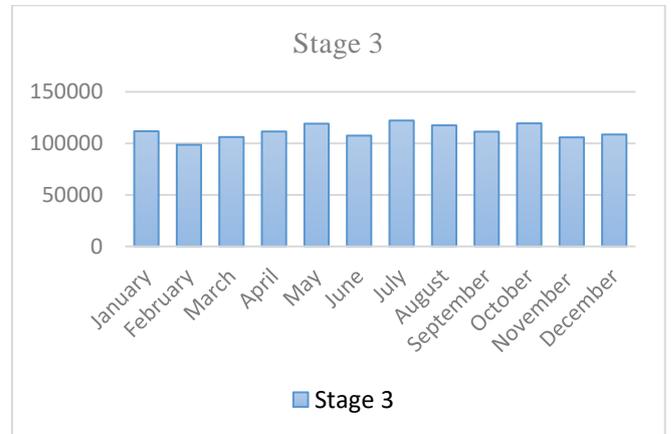

Figure 14: Stage 3 monthly energy consumption simulated on DesignBuilder software- By researcher

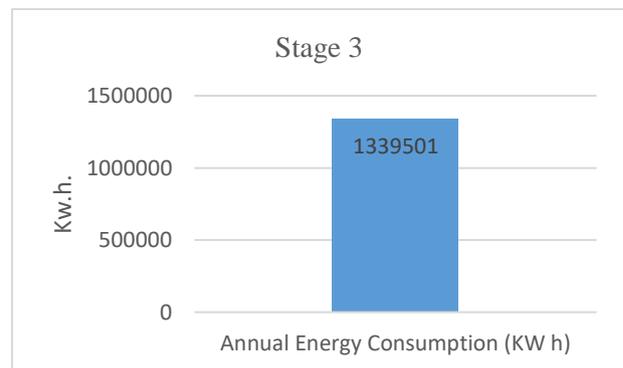

Figure 15: Stage 3 annual energy consumption simulated on DesignBuilder software- By researcher

The integration of the Jonsol JSM-72 PV modules with cell efficiency 19 % in the building skin on an area of 680.74 m2 resulted in the following reductions. The annual energy consumption was reduced from 1414229 KW.h to

1339501 KW.h with a reduction of 5.2% of the total energy consumption as shown in figure 15.

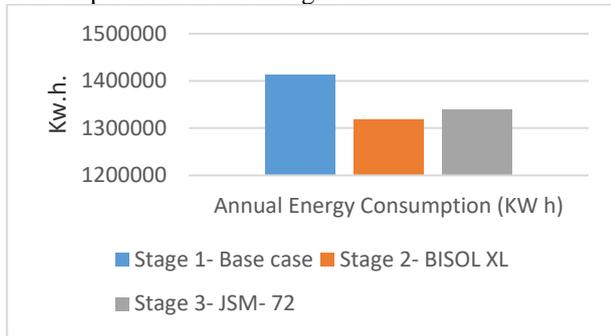

Figure 16: Annual energy consumption simulated on DesignBuilder software for the three stages- By researcher

The comparative study presented at this scientific research by applying retrofit strategies to the building envelope by partially replacing it with Photovoltaic modules.

In stage 1, a base case simulation study was held in order to determine the annual energy consumption as a benchmark to measure the extent to which the energy consumption will be affected by using photovoltaic cells. The simulation of the base case model of the building shows that the annual energy consumption rate is 1414229 KW.h.

In stage 2, the partial replacement of the building envelope with BISOL XL Series achieved energy saving of a cost of 9648.4 \$ per year with an initial cost of around 55564 \$ and a payback period of 5.8 years.

In stage 3, the partial replacement of the building envelope with Jonsol JSM-72 achieved energy saving of a cost of 7472.8 \$ per year with an initial cost of 48550 \$ and a payback period of 6.5 years.

Stage two proved more efficiency and feasibility because of its higher energy saving potential along with shorter payback period.

Table 4: Retrofit cost for building integrated photovoltaics (BIPV) (Stages 1 & 2) [22][24]

Unit	Area (m ²)	Cost/pieces (USD)	Number of pieces	Total cost (USD)
BISOL XL Series	680.74	159.21	349	55564
Jonsol JSM-72	680.74	138.32	351	48550

Table 5 Energy saved and payback period for Stage 2 (BISOL XL Series) [22]

BISOL XL Series	680.74 m ²
Cell efficiency	17.5 %
Total cost	55564 \$
Electricity price	0.10 / KWH
Generated electricity	96484 KWH
Savings	96484 * 0.1 = 9648.4 per year
Payback period	55564 / 9648.4 = 5.8 years

Table 6 Energy saved and payback period for Stage 3 (Jonsol JSM-72) [24]

Jonsol JSM-72	680.74 m ²
Cell efficiency	17.3 %
Total cost	48550 \$
Electricity price	0.10 / KWH
Generated electricity	74728 KWH
Savings	74728 * 0.1 = 7472.8 per year
Payback period	48550 / 7472.8 = 6.5 years

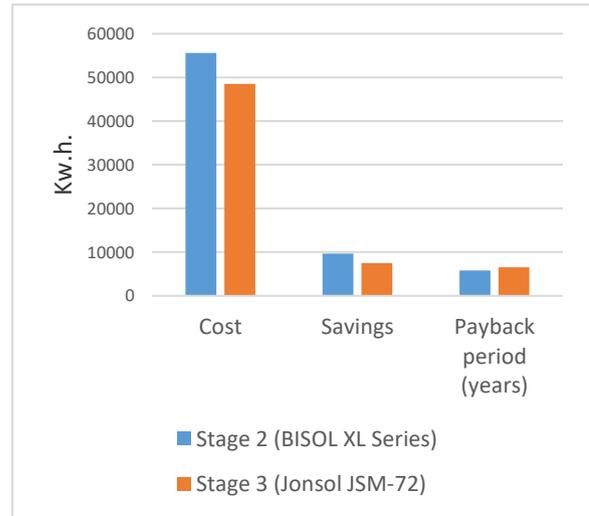

Figure 17: Stages 2 and 3 comparison (cost, savings and payback period)

7. CONCLUSIONS

The comparative study held in this research between two different types of BIPV (building integrated photovoltaics), BISOL XL Series, Multicrystalline PV modules/ BXU 340 Wp and Jonsol JSM-72 PV modules. The performance of these modules was good although their placement in a limited area of the building envelope. Building envelope thermal properties are significant factors determining the buildings' energy consumption rates. This result in the fact that retrofit strategies applied to the building envelope components have a great impact on the energy consumption of buildings. The integration of photovoltaic modules in the building envelope is very suitable in Egypt and MENA (Middle East and North Africa) region in general due to the high solar radiation at this area. Energy simulation studies are a reliable means of holding computer analysis of the energy performance of buildings and the retrofit strategies applied to them. According to the energy simulation processes that were held in this research paper, the performance, savings and payback period of using BISOL XL Series is better and has bigger energy saving potential.
